

*Radiative Effects of MODIS Microphysical and
Dynamical Cloud Regimes in Different Aerosol
Environments as Seen by CERES*

Lazaros Oreopoulos (NASA-GSFC)

Nayeong Cho (USRA/NASA-GSFC)
Dongmin Lee (Morgan State/NASA-GSFC)

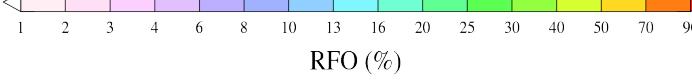

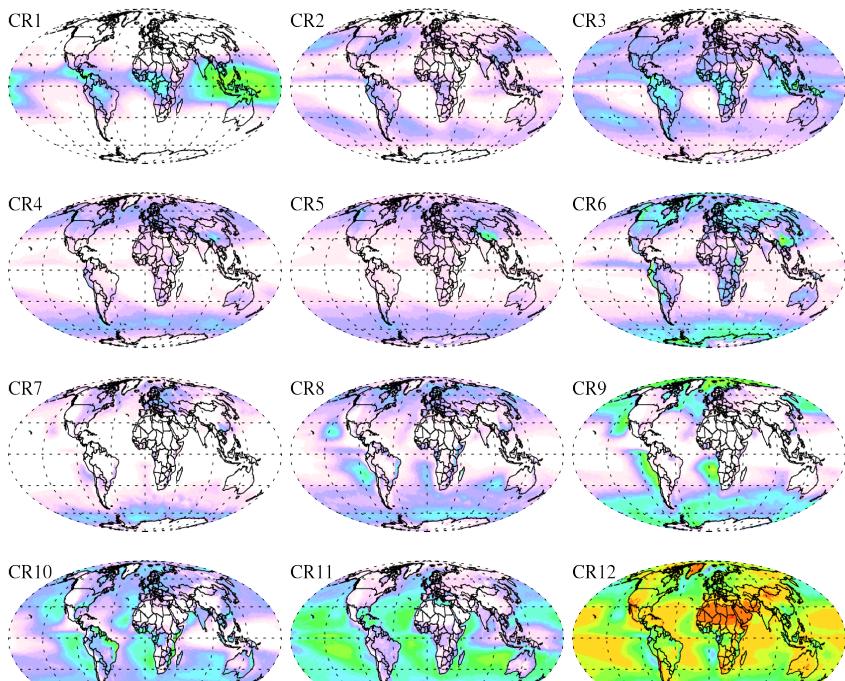

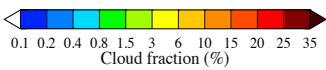

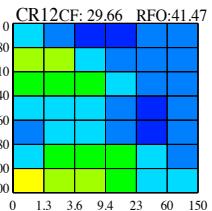

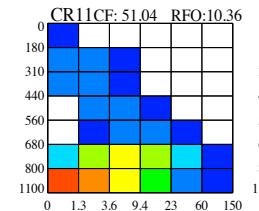

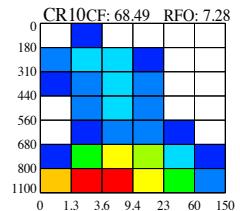

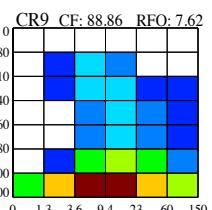

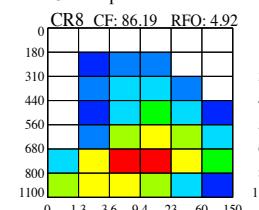

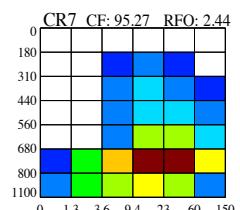

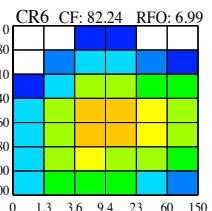

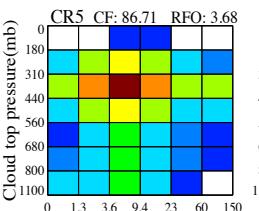

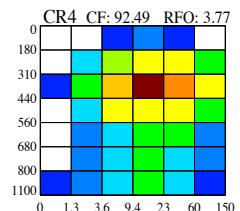

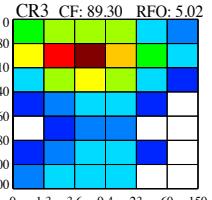

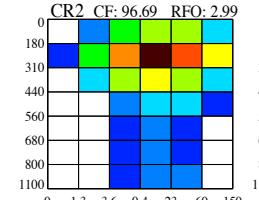

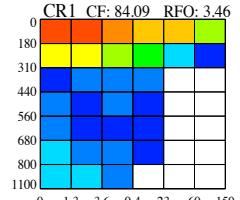

Motivation and approach

- Interpretation of aerosol-cloud interactions from space is difficult.
- How to separate aerosol from all other effects?
- Nevertheless, apparent systematic relationships can perhaps be diagnosed at *global* scales, especially with respect to radiative signals
- Breakdown by “cloud regime” (representative of similar cloud conditions) may help streamline the analysis
- How to define regimes?
 - Exploiting cloud appearance from space is one option
 - Should pose some constraint on environmental conditions
- Our “Cloud Regime” (CR) of choice is based on CTP-COT joint histograms
 - From MODIS (you may also know ISCCP “Weather States”)
- Radiative signals primarily from CERES

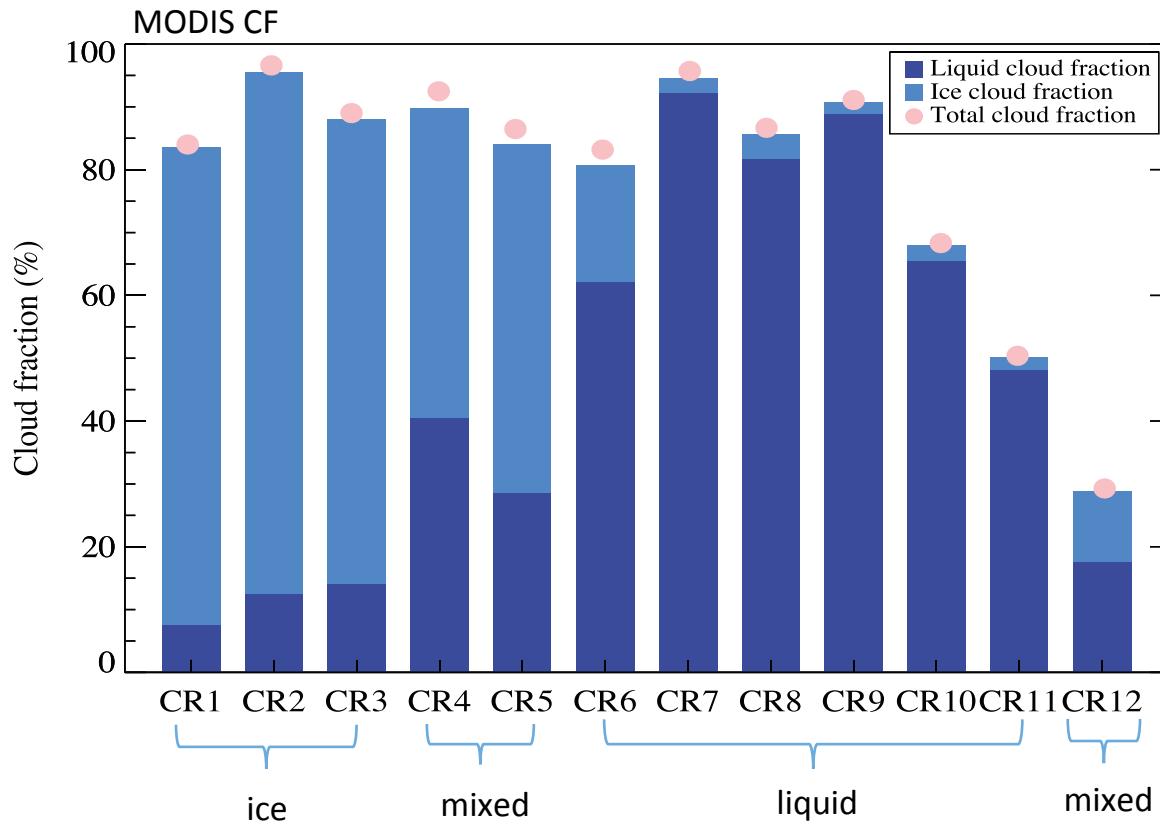

MODIS Collection 6 Cloud Regimes (CRs)

CR thermodynamic phase

Datasets

- **12 years** of Aqua-Terra L-3 daily (D3) 1° data
 - Collection 6
- Joint histograms of CTP-COT
 - MODIS CRs from *k-means* clustering:
- CERES SYN1deg-daily clear and all-sky fluxes; CREs
 - AIRS L3 spectral cloudy and clear OLRs
- Other cloud variables from MODIS: CF, CTP (CTH), COT
- MODIS “Dark Target” AOD (no AI over land, no CCN)
 - 50°S-50°N
- “High volume” study

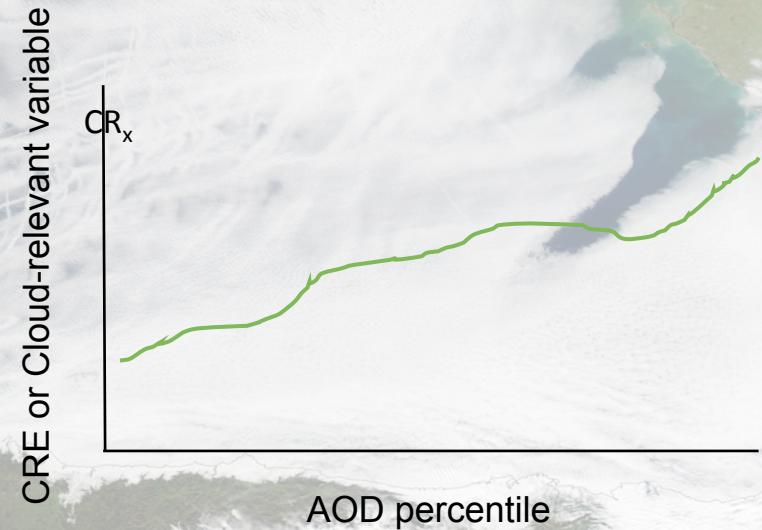

Methodology

- Daily MODIS aerosol AOD defined for each gridcell from Terra and Aqua (neighboring grid cells can be used)
- Define relative AOD (position within distribution for *that location/gridcell and season, independent of CR*)
- Identify **CRE**, CF, CTP, COT, CER vs collocated aerosol for *each* CR occurrence
- Average all values within the same AOD percentile and for the same CR
- CERES SYN1deg fluxes are daily averages, AIRS at 1:30 pm
- Generally different CRs for Terra and Aqua for the same day and gridcell

	Aqua AOD1	
	Nan	
Aqua AOD2		

	Terra AOD3	
	Nan	

$$AOD = (AOD1 + AOD2 + AOD3) / 3$$

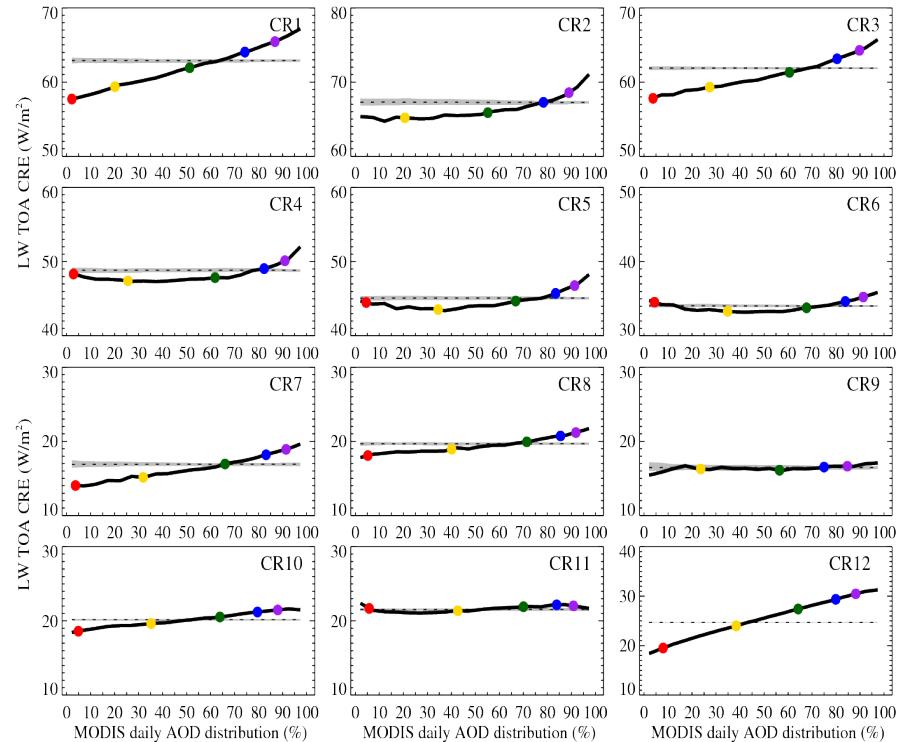

LW CRE increases with AOD almost always

Ocean

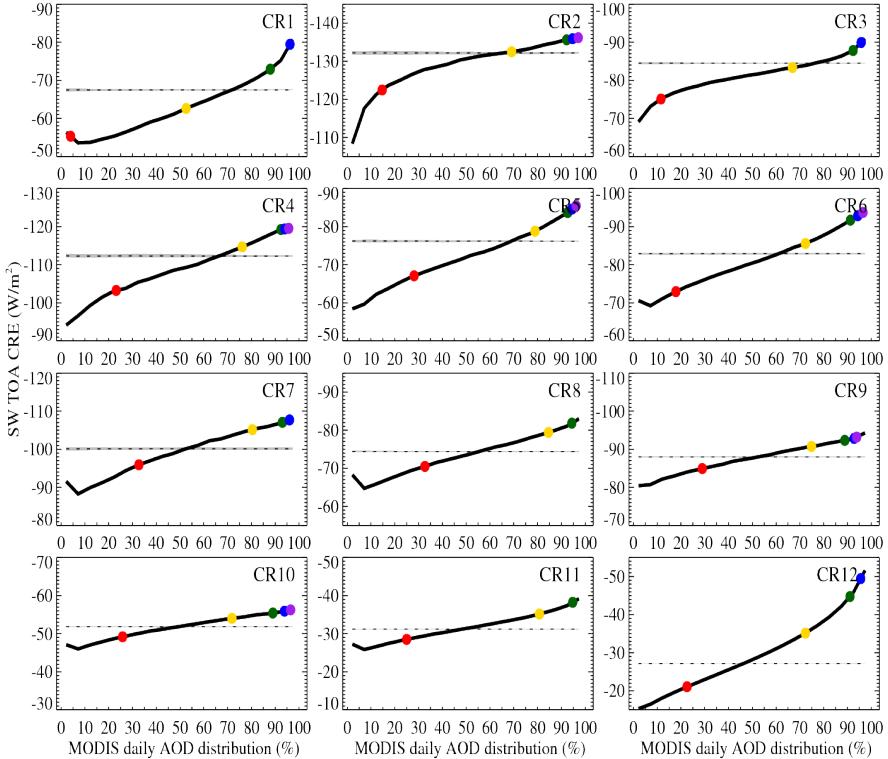

Land

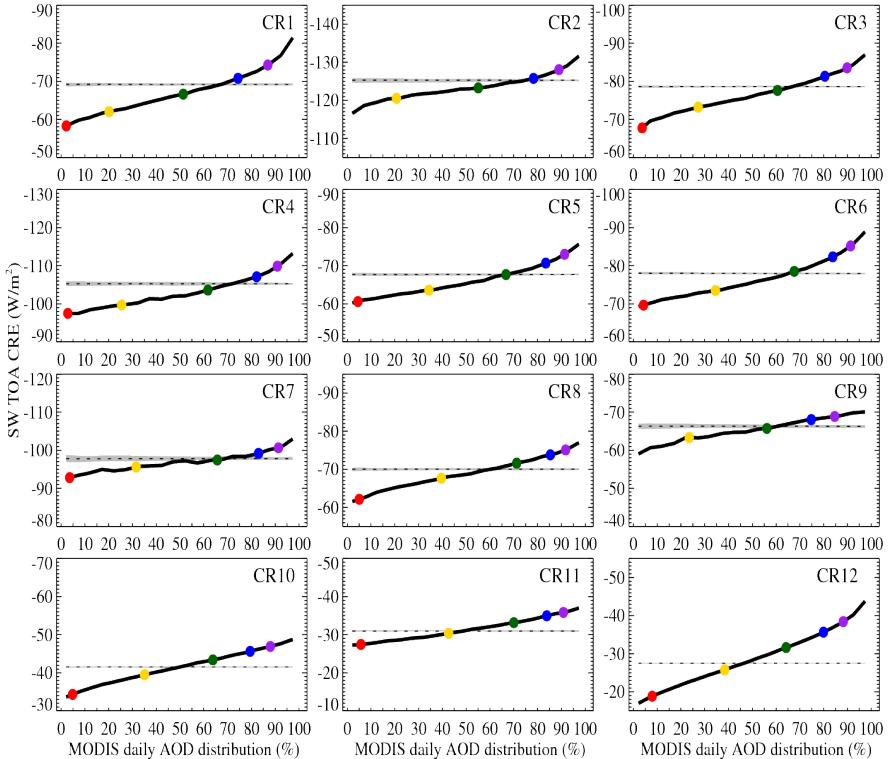

SW CRE increases with AOD almost always

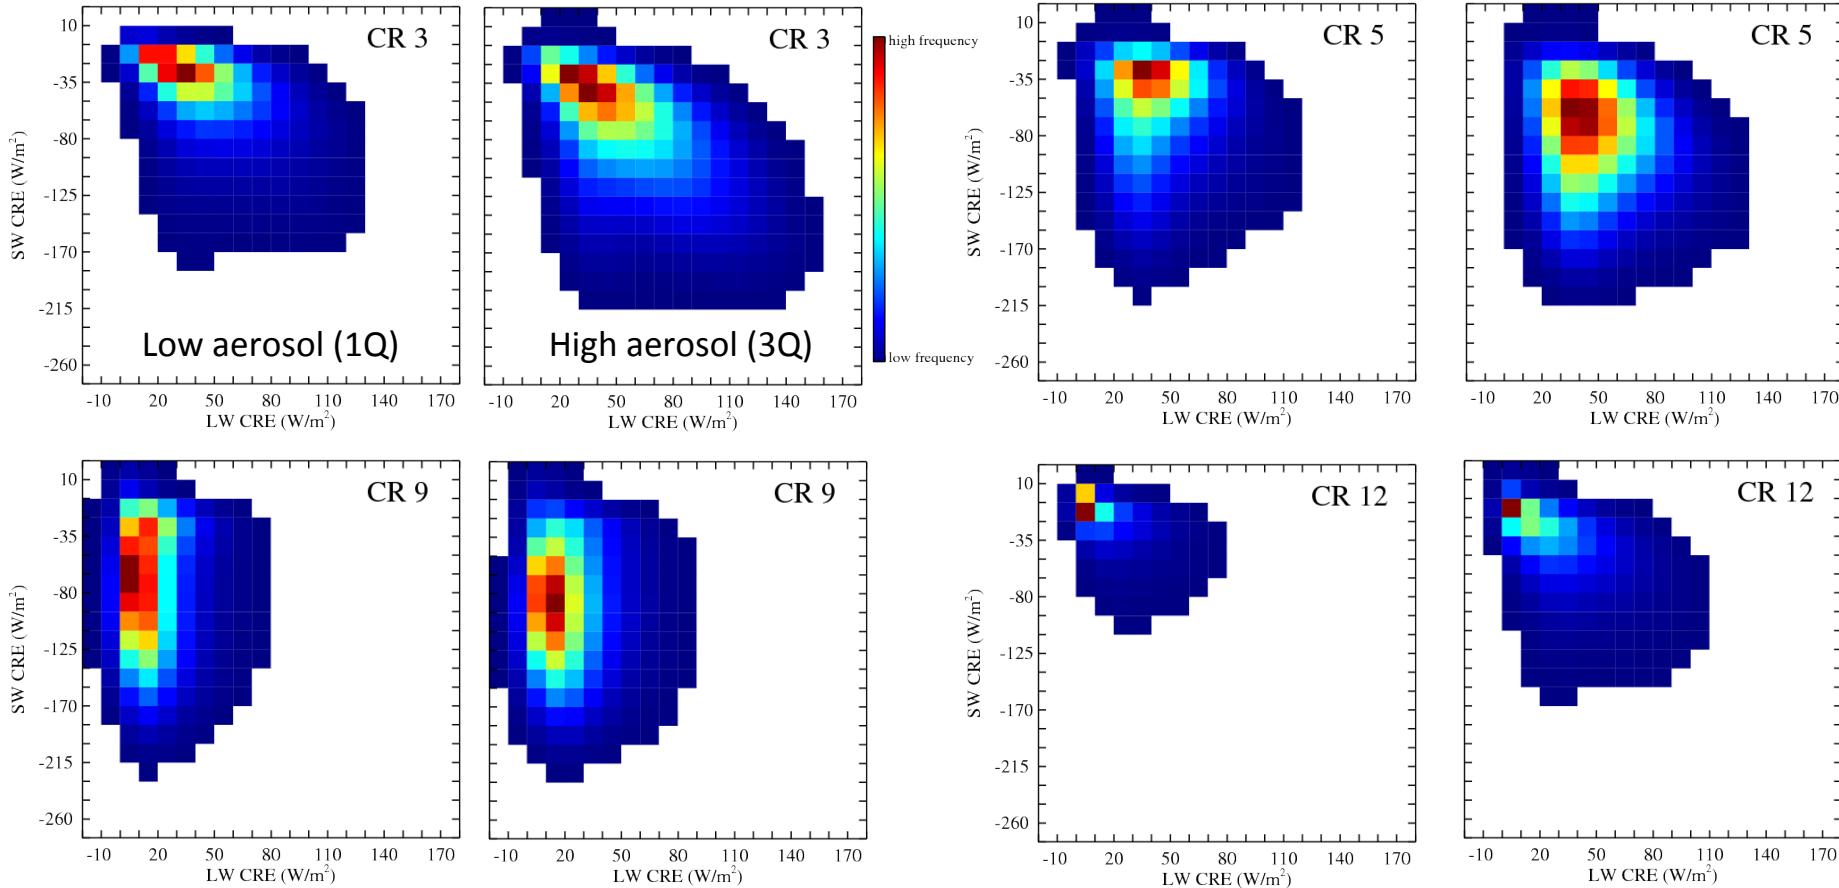

Ocean

Land

Joint PDFs of LW and SW CRE (ocean): peaks shift towards higher values and distributions widen

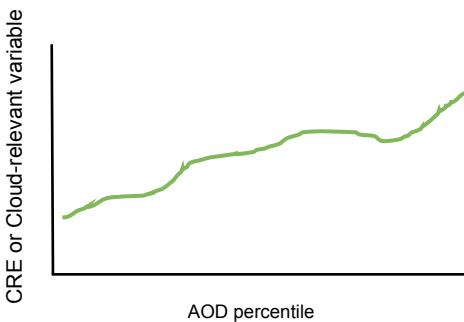

CRE changes are generally consistent with cloud property changes

$$CRE_{LW, SW} = CF[F_{clr}(AOD) - F_{ovc}(COT, CTH)]$$

	Ice (CR1-CR3)		Liq (CR6-CR11)		Mix (CR4-CR5)		CR12	
	Ocean	Land	Ocean	Land	Ocean	Land	Ocean	Land
CF		↑		↑		—		↑
COT	—	↑	↑	↑	↓	↑	↑	↑
CTH	↑		↑	↑	↑	↓	↑	↑
SW CRE	↑		↑		↑		↑	↑
LW CRE	↑		↑		↑		↑	↑

red arrow: consistent with invigoration
blue arrow: consistent with 1st and 2nd indirect effect

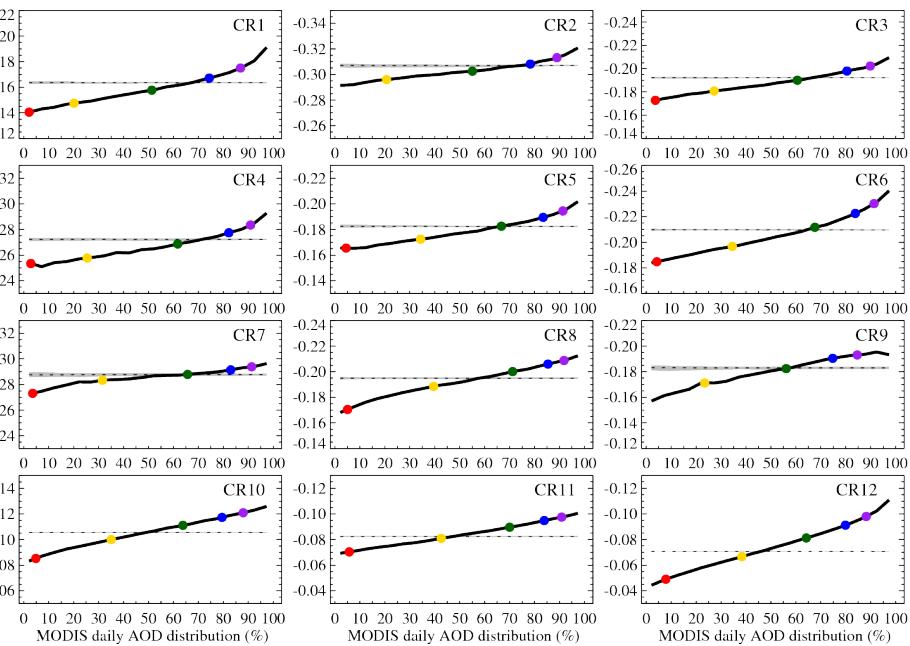

When normalized, CRE SW correlation with relative AOD weakens (ocean)

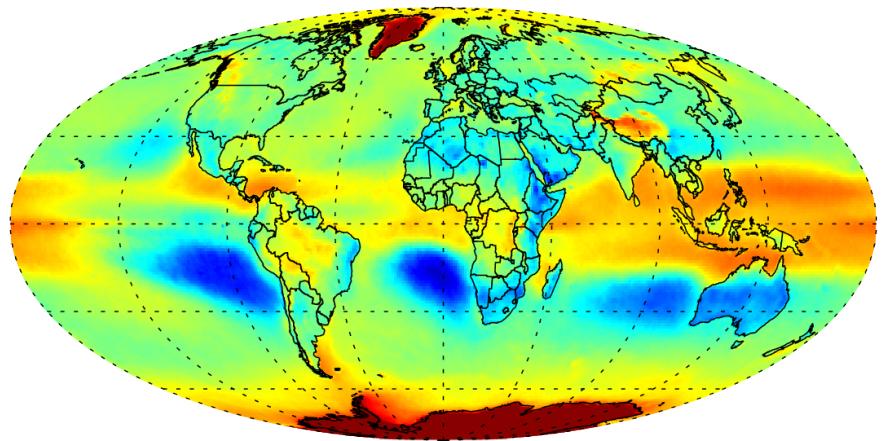

Ocean

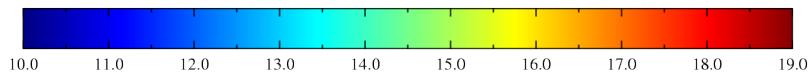

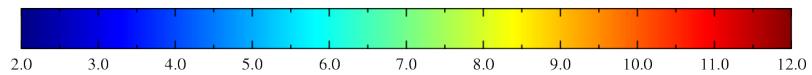

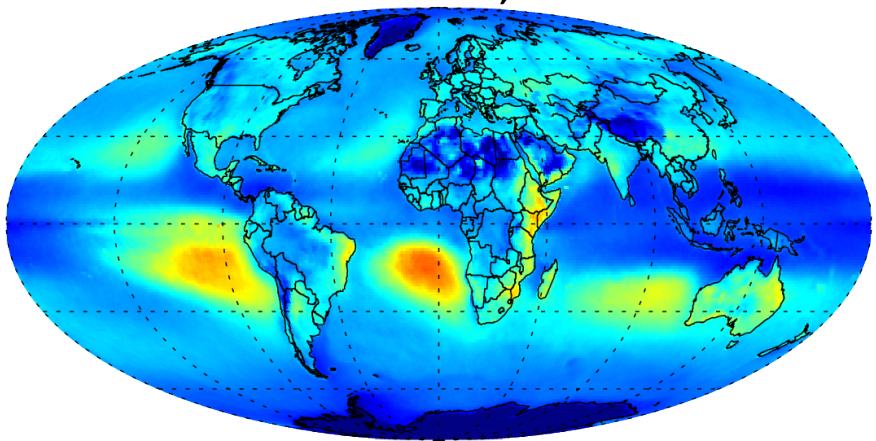

Land

AIRS RRTM band 2, 350-500 cm⁻¹

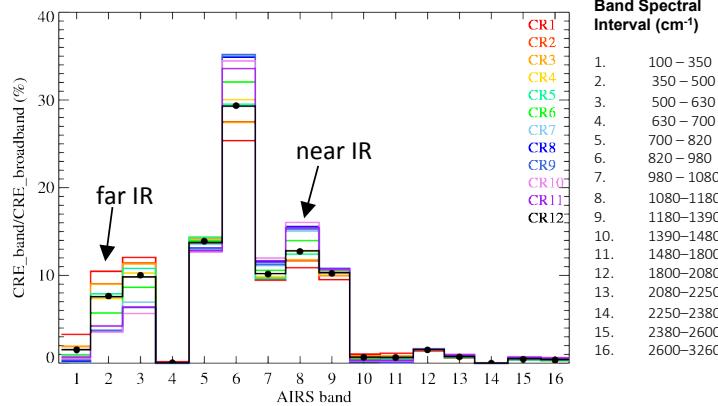

AIRS RRTM band 8, 1080-1180 cm⁻¹

Global spectral CRE
fraction by MODIS CR

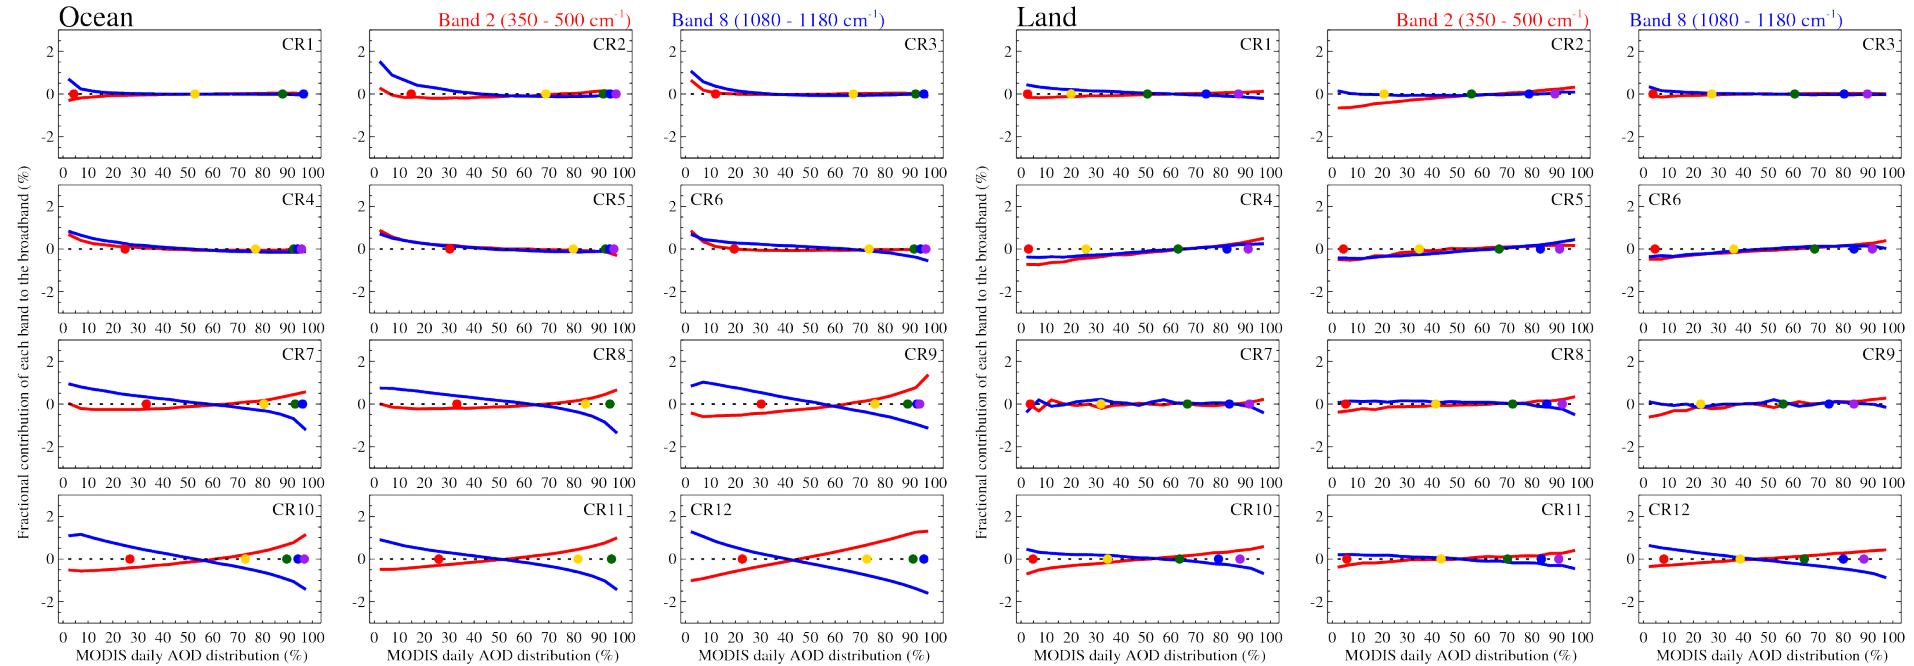

$$f_{\Delta\nu} = \frac{OLR_{clr}(\Delta\nu) - OLR_{ovc}(\Delta\nu)}{OLR_{clr} - OLR_{ovc}}$$

cloud tops rising:

- far IR ratio increasing
- near IR ratio decreasing

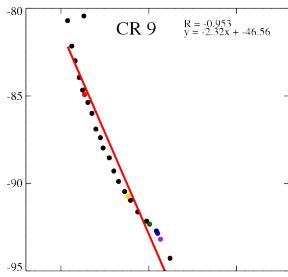

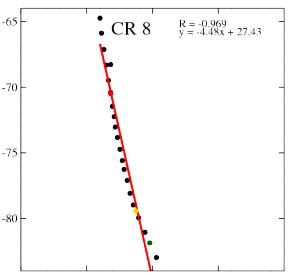

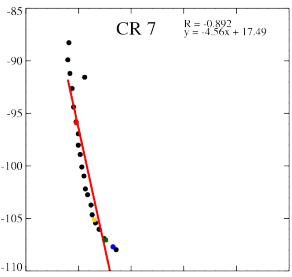

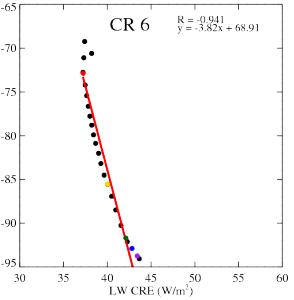

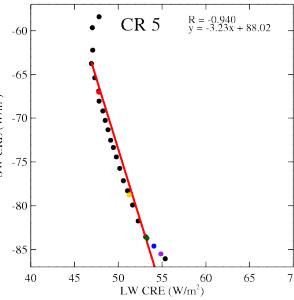

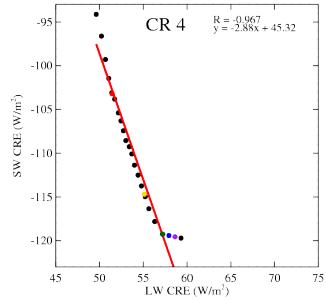

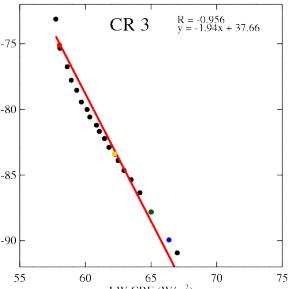

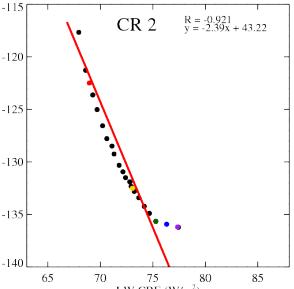

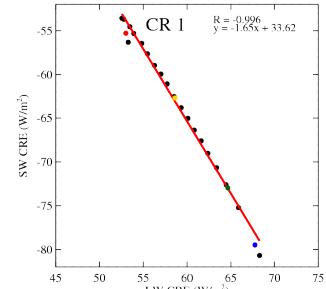

No spectral CRE ratio signals for high-cloud CRs

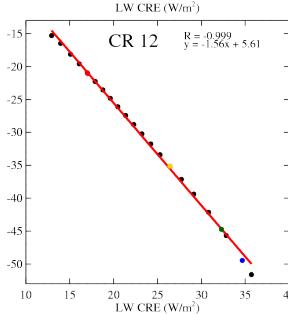

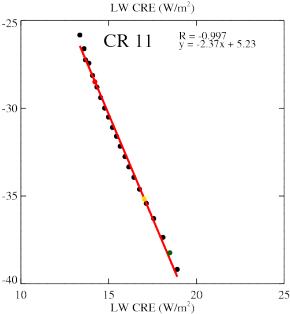

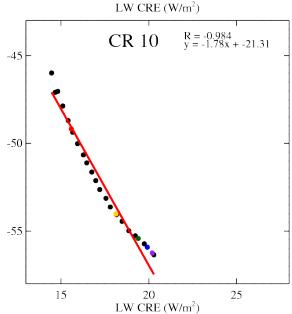

cloud tops rising:

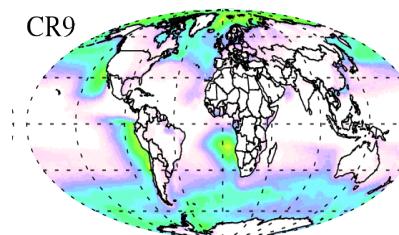

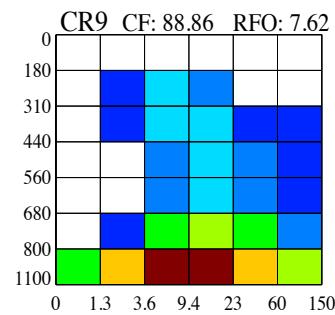

- far IR increasing
- near IR decreasing

Ocean only

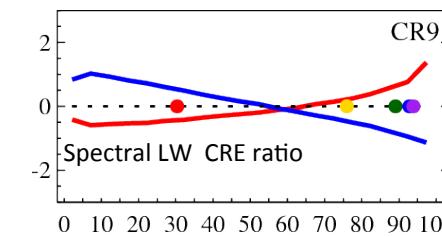

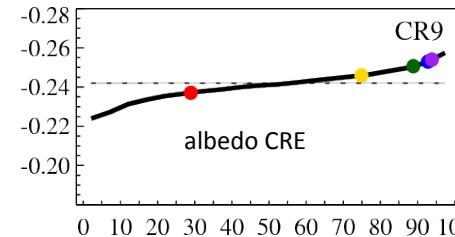

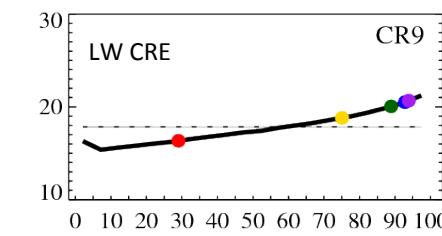

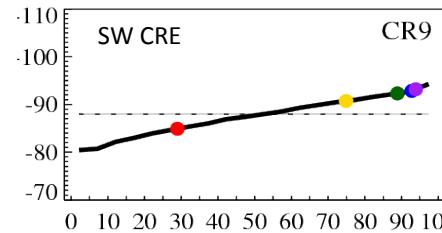

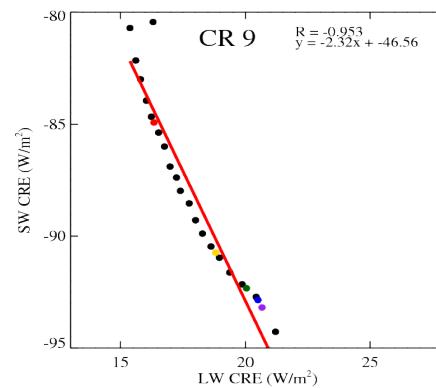

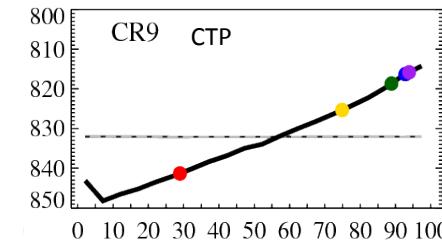

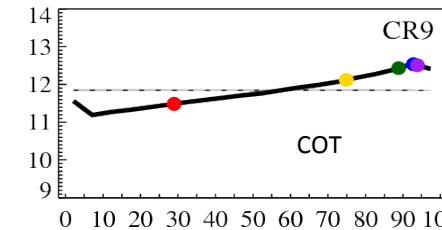

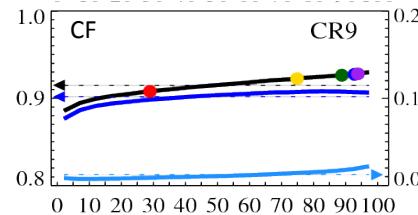

Deviations from straight line
indicative of non-CF cloud changes

The full picture for a low-cloud regime (ocean)

Take-home messages

- Regime-based approach is suitable for *diagnosis* of aerosol-cloud interactions at (near) global scales
- CRE variability with AOD seems very systematic ("good looking" curves) and largely consistent with cloud property changes. Interpretation challenges remain
- CRE variability consistent with invigoration, 1st and 2nd indirect effects
- Despite use of relative values, effects of any AOD retrieval biases under varying cloud conditions remain.
- More details in Oreopoulos et al. JGR (2017).
